**COURSE PLAN – PART II****COURSE OVERVIEW**

Most industries today are being equipped with electrical drives and locomotives thanks to the easy controllability and modular structure. This creates an urge among the electrical engineers to know about the basics of electrical machines, in particular ac machines since they are used in most industrial drives. These electric drives are well known for their flexible and effective controllability. Hence it also becomes important to know about the methods of implementing various speed control techniques and braking mechanisms for these machines.

Such requirements have motivated us to frame this course as a core course for electrical engineering students. This course syllabus has been framed such that the initial topics deal with the constructional details and working principle of the rotating ac machines and upon completion would help the students to choose appropriate machine for various industrial applications. After designing any machine, it becomes inevitable to validate the design and hence an appropriate model for any machine becomes necessary. Hence equivalent circuit model is also being given focus in this course and further analysis of the performance of the machine is also given focus.

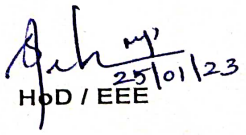

Hence on completion of this course a B.Tech. student upon graduating as an Electrical Engineer would have a basic knowledge of the choice of appropriate ac machine drive for various industrial applications with appropriate control strategy.
